

Fuel Effects on Particulates from Modern Gasoline Vehicles

Heather Hamje

Concawe, **Brussels**

HEI Workshop

Chicago, 8th December 2016

- It has been known for some time that gasoline direct injection (GDI) vehicles produce more particulate number emissions than port fuel injected equivalents and DPF equipped diesel engines
- From 2014 limits on particulate number were introduced for Euro 6 GDI vehicles which by 2017 will be equivalent to those that exist for diesel vehicles (6 x 10¹¹#/km)
 1.0E+14 =
- In addition, the EU Renewable Energy Directive and Fuels Quality Directives have promoted increased use of biofuels in Europe
 - Specifications exist for
 - ▶ E5/E10, E85 for gasoline
 - B7, B10 and up to B20 and B30 for diesel

Real Driving Emission (RDE) legislation in Europe has started to take effect from 2016 onwards

WLTP will also be introduced in the near future to replace NEDC

RDE testing will be carried out on typical market fuel

- Concawe has conducted several studies involving particulates:
 Two gasoline passenger cars were tested over the NEDC test cycle for regulated emissions, PM, PN and fuel consumption (*Concawe report 10/16, June 2016*)
 - Fuel Matrix covering range of RON, different oxygenate types and O content
 - Matched and splash blended fuels
 - Two studies have also been conducted in conjunction with AECC (catalyst manufacturer's association)
 - 1) Comparison of NEDC, WLTP and on-road RDE cycles on commercial Gasoline DI vehicle fitted with GPF (*3rd International conference on RDE emissions, Berlin, 2015*)
 - 2) Second study focused more on RDE including on-road and simulated chassis dyno testing on Gasoline DI vehicle with and without GPF (*paper for SAE 2017 World Congress*)
 - Studied diesel properties on PM and other emissions
 - On Euro, 4,5 & 6 vehicles over NEDC and WLTP (SAE PF&L, Paper SAE 2016 – 01-2246)

GDI Particulates Study Experimental Set Up

Objective: Investigate the effect of fuel properties on particulates and other emissions from modern gasoline DI vehicles

Particulate number and distribution measured using the PMP protocol with cyclonic separator, two thermo diluters in series followed by CPC

- Two vehicles were tested using the NEDC protocol
 - Euro 4 2.4litre NA 6-cylinder DI with TWC
- Reproduction permitted with due acknowledgement Euro 5 - 1.8litre TC 4-cylinder DI with TWC

E20

Splash blending gave directional reduction in PN as ethanol content Reproduction period creases, only significant in one vehicle but no significant effect on PM with due acknowledgement

Fuel Effects on Particulates from Modern Gasoline Vehicles Heather Hamje

Ethanol Effects on PN and PM matched at RON95

No significant effects - directional increase in PM and PN with increased with due acknowledgemethanol

Fuel Effects on Particulates from Modern Gasoline Vehicles Heather Hamie

Matched RON98 blends with and without oxygenates

Vehicle 1

Ē

Oxygenate blends showed lower PN at similar octane in both vehicles but only

 With due acknowledgement BE PM result on one vehicle was significant

Fuel Effects on Particulates from Modern Gasoline Vehicles Heather Hamje

Particle Number Distribution

Vehicle 2 has higher PN than Vehicle 1 for all fuels

Indication of bi-modal distribution although limitations on the detection limit of the equipment for nano-particulate detection

Error bars (not shown) too great to distinguish trends between fuels

Fuel Effects on Particulates from Modern Gasoline Vehicles Heather Hamje Ē

- Various indices exist which try to correlate fuel properties with particulates
- One of the simpler of these was developed by Jaguar Landrover
- Calculated from the % of paraffins, olefins, aromatics, oxygenates, DVPE

PN Index =
$$\frac{\sum_{i=1}^{n} [DBE_{i}+1]V_{i}}{DVPE (kPa)} (kPa^{-1})$$

SAE 2013-01-1558

Oncawe/AECC GDI (2) RDE PN test programme set-up

- Objective: investigate NOx & PN RDE without and with Gasoline Particulate Filter (GPF)
 - Vehicle C-segment, 1.4I engine
 - Market representative GDI technology targeting Euro 6c, only Euro 6b available
 - Original configuration w/o GPF
 - Add coated GPF demonstrator underfloor
- HORIBA PEMS equipment
 Gaseous PEMS (CO₂, CO, NOx) + PEMS-PN demo unit
- Additional investigations (not discussed here)
 - Effect of severity of RDE

Reproduction permitted 7nm vs 23nm cut-off

Underfloor view

Fuel Effects on Particulates from Modern Gasoline Vehicles Heather Hamie

19

- In general fuel effects on emissions were fairly small compared to vehicle-vehicle differences
- Some indications that increasing oxygenates decreased PN emissions
 - Splash-blended fuels showed directional reduction but reductions were significant in only one vehicle in the Concawe study
 - Fuels matched at 95 RON showed no significant effects and directionally PN increased with increasing ethanol up to 10%
 - Fuels matched at 98 RON showed significant reduction mainly on PN
- The PM measurements are low and at the limit of the test capability which may explain why some effects were "seen" in PN but not PM
- Concawe/AECC study (2) gave mixed results comparing E5 market and E10 reference fuels
- PN index (JLR) showed some correlation with PN number but fuels at extremes of vapor pressure did not correlate well
- ► Use of GPF was successful in reducing PN emissions below the Euro Reproduction permitted 6c and proposed 6d limits

- The Concawe study showed different levels of correlation with PN Index in the two different vehicles studied
 - PM/PN indices are of interest but more work is needed to understand how they correlate with a wider range of vehicles
 - The indices proposed so far seem to rely heavily on the vapor pressure, other properties may be better predictors of PN number
- Recent Concawe work (unpublished) has suggested that GPF efficiency for filtration of smaller particulates (sub 23nm) is higher than larger particulates
 - More work is needed to understand numbers at these low particle sizes
 - Requires test development work before fuel effects can really be studied
